

On the development and application of weather models for wind energy

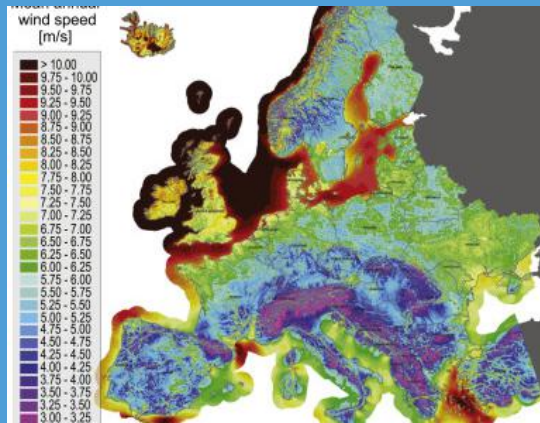

Part 2: Peter Kalverla, Wageningen University

“EUROS for wind energy” – 11 October, 2017

Use of (mesoscale) meteorological models

Among others:

Resource assessment

Rodrigues et al., 2015

(Power) forecasting

e.g. Foley et al., 2012

Realistic inflow fields

Sanz Rodrigo et al., 2017

Need for validation

A model is only of use if its
quality has been quantified,
documented and communicated
to (potential) users

- COST-732 protocol (modified)

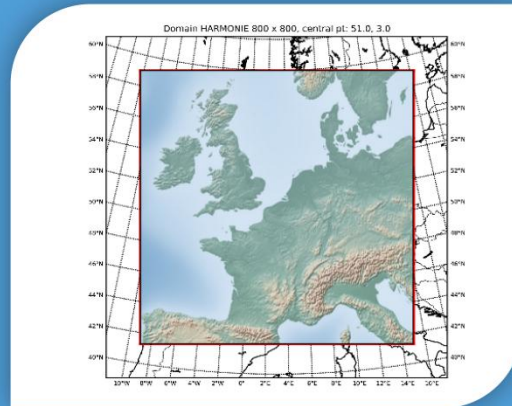

Research questions

- § What is the typical performance of each model?
- § What are the differences between the models?
- § What are the differences between cases?

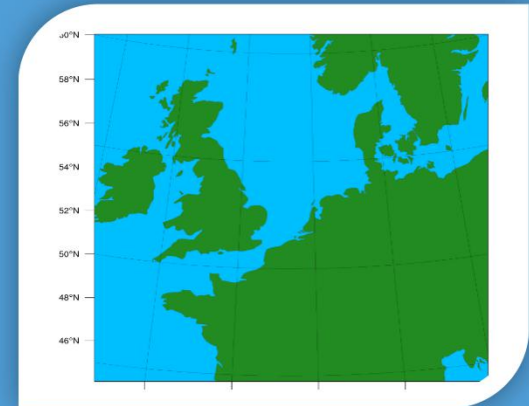

ECMWF-IFS

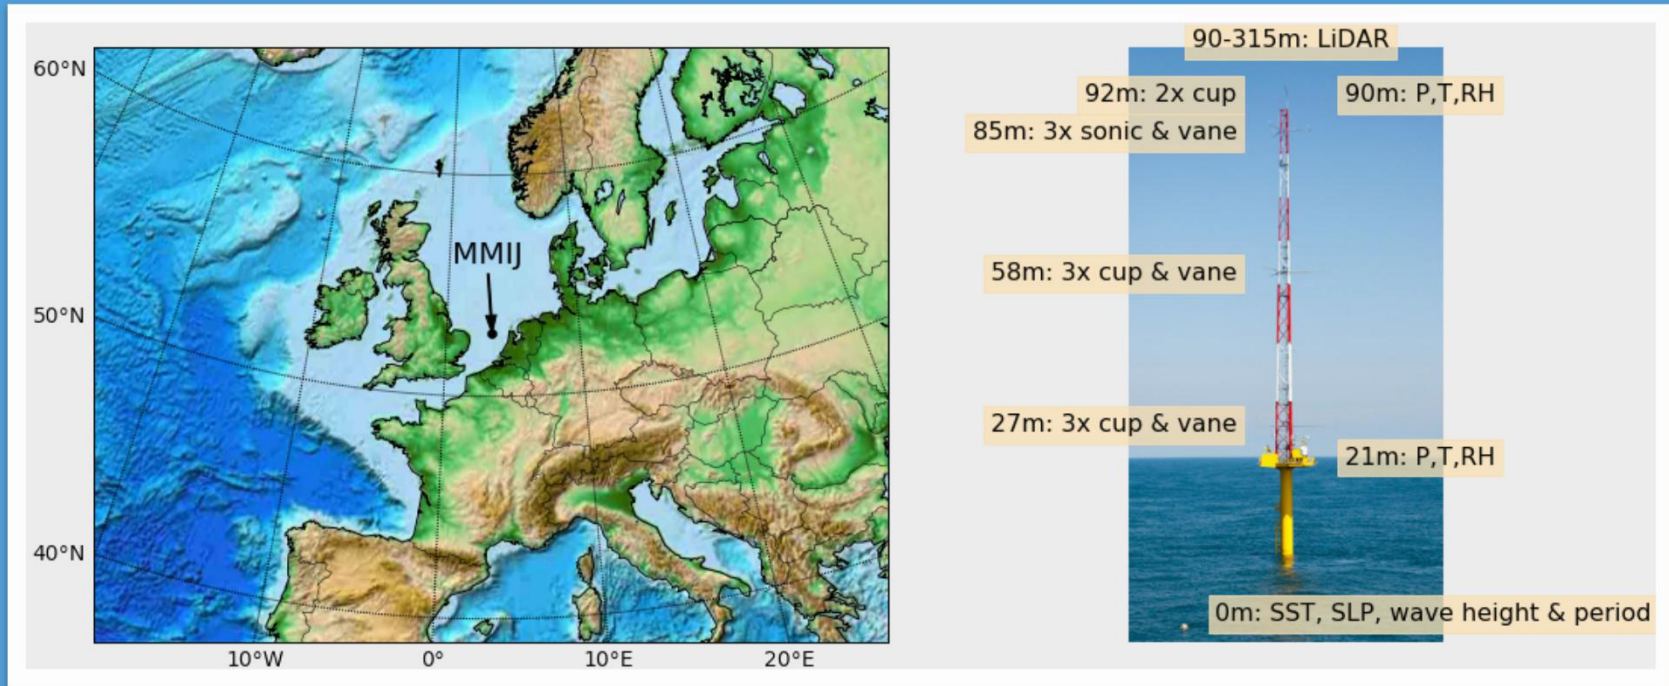

Harmonie (KNMI)

WRF-ARW

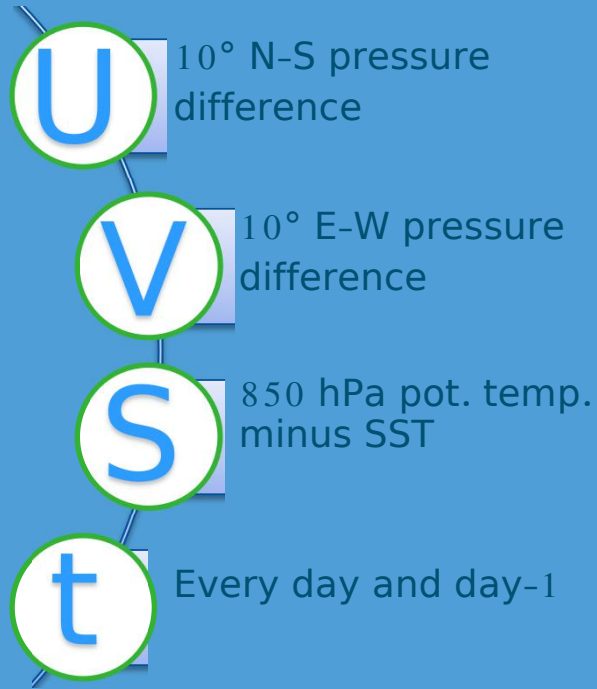

Data for validation: MeteoMast IJmuiden (MMIJ)

Kalverla et al., 2017, JWEIA – An observational climatology of anomalous wind events ...

Case selection strategy: “UVS•t₂” clustering

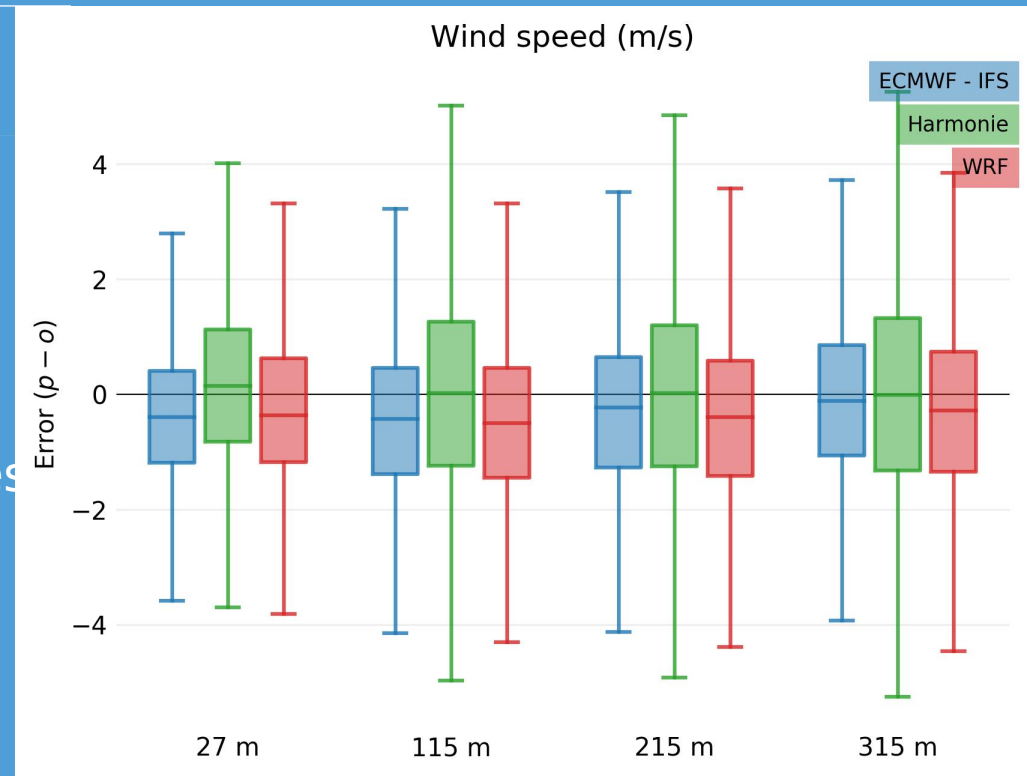

Weighted results

All bias: < 0.5 m/s

Typical spread: < 2 m/s

Harmonie: smallest bias, largest spread

Weighted results

IFS 1 K too warm

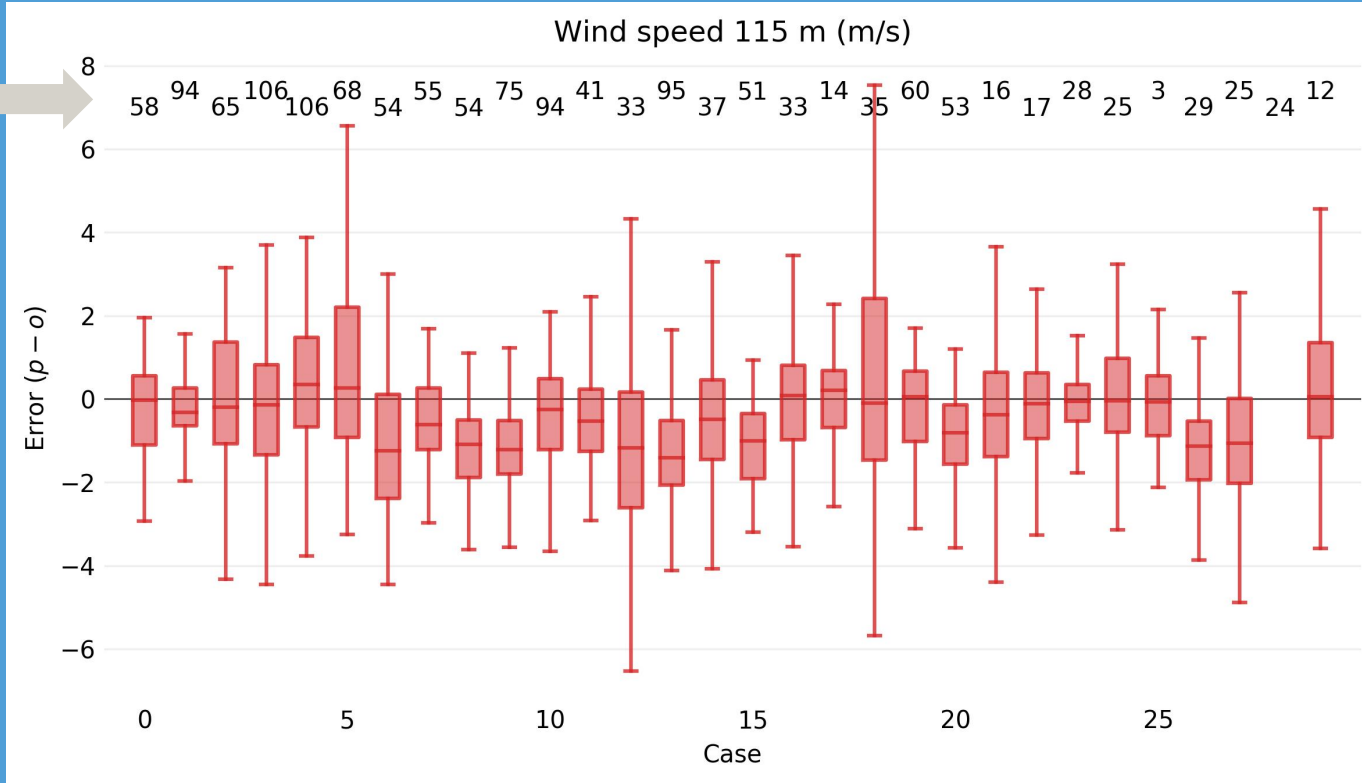

Others too cold

IFS much larger spread

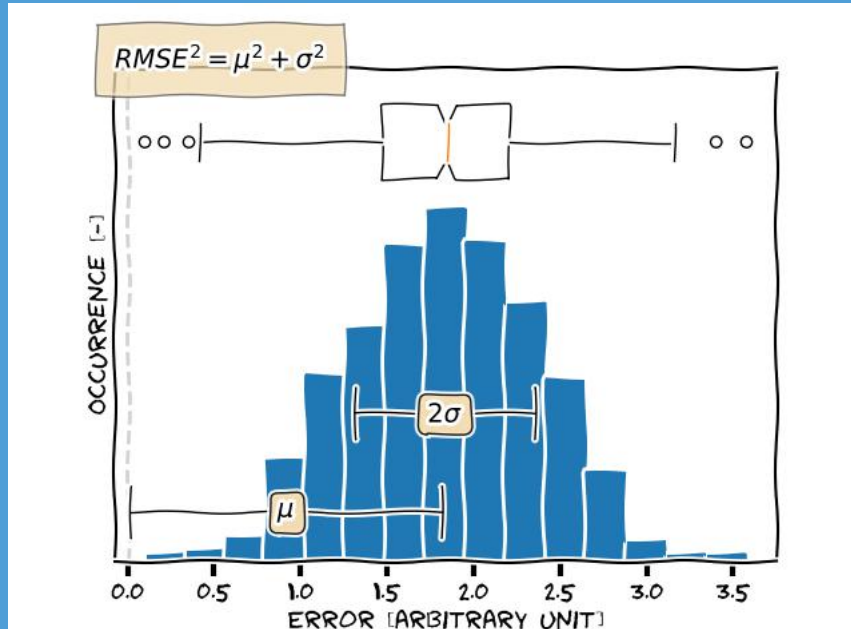

Results per case

Number of cases in cluster

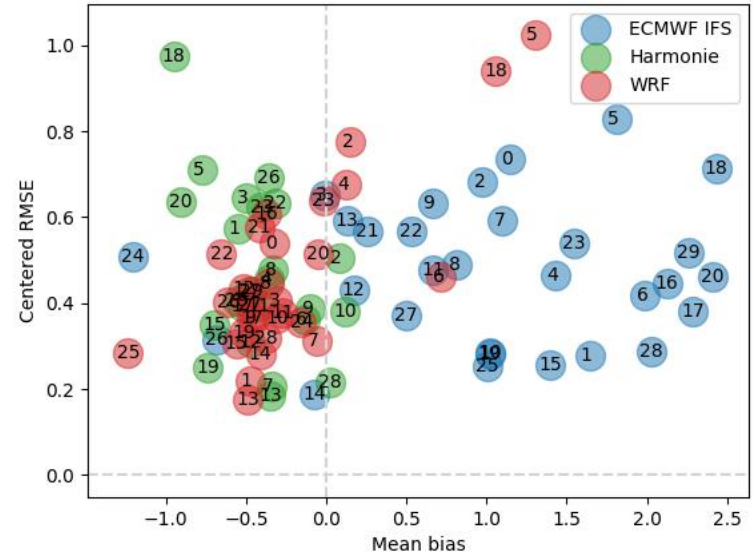

Introducing error diagrams

For quick comparison of 1st and 2nd moments of error distributions

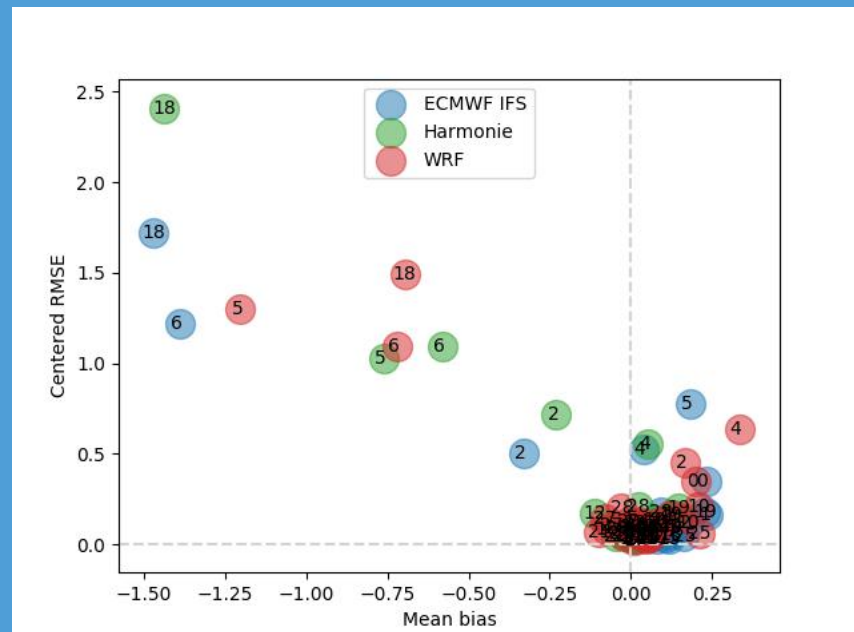

21m potential temperature

Models struggle to represent stable conditions

315m – 27m wind speed difference

90m – 21m virtual potential temp. diff.

Roadmap

Can we understand this behaviour?

How can model performance be improved?

Low-level jets and strong shear both common under stable conditions in spring and summer

Models perform poorly for stable conditions in spring and summer

"A statistical evaluation of three mainstream weather models against the Ijmuiden observations at the North Sea"

"An observational climatology of anomalous wind events at offshore meteo mast Ijmuiden"

PhD Project

Take home

Wind speed bias < 0.5 m/s

Wind speed error std < 2 m/s

ECMWF temperature bias 1K

Performance “CasE seNsitive”

Stable conditions most challenging
